Abstract

A journaling file system uses a log to record all transactions that take place in the file system, and preserves its integrity in the event of a system crash or power failure. Although it is still possible to lose unsaved changes to files, journaling almost completely eliminates the possibility of file system corruption caused by an unclean shutdown. It also shortens to a minimum the time required for after-failure file system checking. Although the UFS file system employed by FreeBSD does not implement journaling itself, the new journal class of the GEOM framework in FreeBSD 7.X can be used to provide file system independent journaling. This article explains how to implement UFS journaling on a typical desktop PC scenario.

1. Introduction

While professional servers are usually well protected from unforeseen shutdowns, the typical desktop is at the mercy of power failures, accidental resets, and other user related incidents that can lead to unclean shutdowns. Soft Updates usually protect the file system efficiently in such cases, although most of the times a lengthy background check is required. On rare occasions, file system corruption reaches a point where user intervention is required and data may be lost.

The new journaling capability provided by GEOM can greatly assist in such scenarios, by virtually eliminating the time required for file system checking, and ensuring that the file system is quickly restored to a consistent state.

This article describes a procedure for implementing UFS journaling on a typical desktop PC scenario (one hard disk used for both operating system and data). It should be followed during a fresh installation of FreeBSD. The steps are simple enough and do not require overly complex interaction with the command line.

After reading this article, you will know:

- How to reserve space for journaling during a new installation of FreeBSD.

- How to load and enable the `geom_journal` module (or build support for it in your custom kernel).
- How to convert your existing file systems to utilize journaling, and what options to use in `/etc/fstab` to mount them.
- How to implement journaling in new (empty) partitions.
- How to troubleshoot common problems associated with journaling.

Before reading this article, you should be able to:

- Understand basic UNIX® and FreeBSD concepts.
- Be familiar with the installation procedure of FreeBSD and the `sysinstall` utility.

Warning

The procedure described here is intended for preparing a new installation where no actual user data is stored on the disk yet. While it is possible to modify and extend this procedure for systems already in production, you should *backup* all important data before doing so. Messing around with disks and partitions at a low level can lead to fatal mistakes and data loss.

2. Understanding Journaling in FreeBSD

The journaling provided by GEOM in FreeBSD 7.X is not file system specific (unlike for example the ext3 file system in Linux®) but is functioning at the block level. Though this means it can be applied to different file systems, for FreeBSD 7.0-RELEASE, it can only be used on UFS2.

This functionality is provided by loading the `geom_journal.ko` module into the kernel (or building it into a custom kernel) and using the `gjournal` command to configure the file systems. In general, you would like to journal large file systems, like `/usr`. You will need however (see the following section) to reserve some free disk space.

When a file system is journaled, some disk space is needed to keep the journal itself. The disk space that holds the actual data is referred to as the *data provider*, while the one that holds the journal is referred to as the *journal provider*. The data and journal providers need to be on different partitions when journaling an existing (non-empty) partition. When journaling a new partition, you have the option to use a single provider for both data and journal. In any case, the `gjournal` command combines both providers to create the final journaled file system. For example:

- You wish to journal your `/usr` file system, stored in `/dev/ad0s1f` (which already contains data).
- You reserved some free disk space in a partition in `/dev/ad0s1g`.
- Using `gjournal`, a new `/dev/ad0s1f.journal` device is created where `/dev/ad0s1f` is the data provider, and `/dev/ad0s1g` is the journal provider. This new device is then used for all subsequent file operations.

The amount of disk space you need to reserve for the journal provider depends on the usage load of the file system and not on the size of the data provider. For example on a typical office desktop, a 1 GB journal provider for the `/usr` file system will suffice, while a machine that deals with heavy disk I/O (i.e. video editing) may need more. A kernel panic will occur if the journal space is exhausted before it has a chance to be committed.

Note

The journal sizes suggested here, are highly unlikely to cause problems in typical desktop use (such as web browsing, word processing and playback of media files). If your workload

includes intense disk activity, use the following rule for maximum reliability: Your RAM size should fit in 30% of the journal provider's space. For example, if your system has 1 GB RAM, create an approximately 3.3 GB journal provider. (Multiply your RAM size with 3.3 to obtain the size of the journal).

For more information about journaling, please read the manual page of [gjournal\(8\)](#).

3. Steps During the Installation of FreeBSD

3.1. Reserving Space for Journaling

A typical desktop machine usually has one hard disk that stores both the OS and user data. Arguably, the default partitioning scheme selected by sysinstall is more or less suitable: A desktop machine does not need a large `/var` partition, while `/usr` is allocated the bulk of the disk space, since user data and a lot of packages are installed into its subdirectories.

The default partitioning (the one obtained by pressing A at the FreeBSD partition editor, called Disklabel) does not leave any unallocated space. Each partition that will be journaled, requires another partition for the journal. Since the `/usr` partition is the largest, it makes sense to shrink this partition slightly, to obtain the space required for journaling.

In our example, an 80 GB disk is used. The following screenshot shows the default partitions created by Disklabel during installation:

```
FreeBSD Disklabel Editor
Disk: ad0 Partition name: ad0s1 Free: 0 blocks (0MB)
Part      Mount      Size Newfs  Part      Mount      Size Newfs
-----
ad0s1a    /           512MB UFS2   Y
ad0s1b    swap        478MB SWAP
ad0s1d    /var        1263MB UFS2+S Y
ad0s1e    /tmp        512MB UFS2+S Y
ad0s1f    /usr        79151MB UFS2+S Y

The following commands are valid here (upper or lower case):
C = Create      D = Delete    M = Mount pt.
N = Newfs Opts  Q = Finish    S = Toggle SoftUpdates  Z = Custom Newfs
T = Toggle Newfs U = Undo      A = Auto Defaults      R = Delete+Merge

Use F1 or ? to get more help, arrow keys to select.
```

If this is more or less what you need, it is very easy to adjust for journaling. Simply use the arrow keys to move the highlight to the `/usr` partition and press D to delete it.

Now, move the highlight to the disk name at the top of the screen and press C to create a new partition for `/usr`. This new partition should be smaller by 1 GB (if you intend to journal `/usr` only), or 2 GB (if you intend to journal both `/usr` and `/var`). From the pop-up that appears, opt to create a file system, and type `/usr` as the mount point.

Note

Should you journal the `/var` partition? Normally, journaling makes sense on quite large partitions. You may decide not to journal `/var`, although doing so on a typical desktop will cause no harm. If the file system is lightly used (quite probable for a desktop) you may wish to allocate less disk space for its journal.

In our example, we journal both `/usr` and `/var`. You may of course adjust the procedure to your own needs.

To keep things as easy going as possible, we are going to use `sysinstall` to create the partitions required for journaling. However, during installation, `sysinstall` insists on asking a mount point for each partition you create. At this point, you do not have any mount points for the partitions that will hold the journals, and in reality you *do not even need them*. These are not partitions that we are ever going to mount somewhere.

To avoid these problems with `sysinstall`, we are going to create the journal partitions as swap space. Swap is never mounted, and `sysinstall` has no problem creating as many swap partitions as needed. After the first reboot, `/etc/fstab` will have to be edited, and the extra swap space entries removed.

To create the swap, again use the arrow keys to move the highlight to the top of Disklabel screen, so that the disk name itself is highlighted. Then press `N`, enter the desired size (*1024M*), and select “swap space” from the pop-up menu that appears. Repeat for every journal you wish to create. In our example, we create two partitions to provide for the journals of `/usr` and `/var`. The final result is shown in the following screenshot:

```
FreeBSD Disklabel Editor
Disk: ad0      Partition name: ad0s1  Free: 0 blocks (0MB)

Part  Mount      Size Newfs  Part  Mount      Size Newfs
----  -
ad0s1a /           512MB UFS2   Y
ad0s1b swap        478MB SWAP
ad0s1d /var       1263MB UFS2+S Y
ad0s1e /tmp       512MB UFS2+S Y
ad0s1f /usr      77103MB UFS2+S Y
ad0s1g swap       1024MB SWAP
ad0s1h swap       1024MB SWAP

The following commands are valid here (upper or lower case):
C = Create      D = Delete    M = Mount pt.
N = Newfs Opts  Q = Finish    S = Toggle SoftUpdates  Z = Custom Newfs
T = Toggle Newfs U = Undo      A = Auto Defaults      R = Delete+Merge

Use F1 or ? to get more help, arrow keys to select.
```

When you have completed creating the partitions, we suggest you write down the partition names, and mount points, so you can easily refer to this information during the configuration phase. This will help alleviate mistakes that may damage your installation. The following table shows our notes for the sample configuration:

Table 1. Partitions and Journals

Partition	Mount Point	Journal
ad0s1d	/var	ad0s1h
ad0s1f	/usr	ad0s1g

Continue the installation as you would normally do. We would however suggest you postpone installation of third party software (packages) until you have completely setup journaling.

3.2. Booting for the first time

Your system will come up normally, but you will need to edit `/etc/fstab` and remove the extra swap partitions you created for the journals. Normally, the swap partition you will actually use is the one with the “b” suffix (i.e. `ad0s1b` in our example). Remove all other swap space entries and reboot so that FreeBSD will stop using them.

When the system comes up again, we will be ready to configure journaling.

4. Setting Up Journaling

4.1. Executing `gjournal`

Having prepared all the required partitions, it is quite easy to configure journaling. We will need to switch to single user mode, so login as `root` and type:

```
# shutdown now
```

Press Enter to get the default shell. We will need to unmount the partitions that will be journaled, in our example `/usr` and `/var`:

```
# umount /usr /var
```

Load the module required for journaling:

```
# gjournal load
```

Now, use your notes to determine which partition will be used for each journal. In our example, `/usr` is `ad0s1f` and its journal will be `ad0s1g`, while `/var` is `ad0s1d` and will be journaled to `ad0s1h`. The following commands are required:

```
# gjournal label ad0s1f ad0s1g
```

```
GEOM_JOURNAL: Journal 2948326772: ad0s1f contains data.
GEOM_JOURNAL: Journal 2948326772: ad0s1g contains journal.
```

```
# gjournal label ad0s1d ad0s1h
```

```
GEOM_JOURNAL: Journal 3193218002: ad0s1d contains data.
GEOM_JOURNAL: Journal 3193218002: ad0s1h contains journal.
```

Note

If the last sector of either partition is used, `gjournal` will return an error. You will have to run the command using the `-f` flag to force an overwrite, i.e.:

```
# gjournal label -f ad0s1d ad0s1h
```

Since this is a new installation, it is highly unlikely that anything will be actually overwritten.

At this point, two new devices are created, namely `ad0s1d.journal` and `ad0s1f.journal`. These represent the `/var` and `/usr` partitions we have to mount. Before mounting, we must however set the journal flag on them and clear the Soft Updates flag:

```
# tuneefs -J enable -n disable ad0s1d.journal
```

```
tuneefs: gjournal set
tuneefs: soft updates cleared
```

```
# tuneefs -J enable -n disable ad0s1f.journal
```

```
tuneefs: gjournal set
tuneefs: soft updates cleared
```

Now, mount the new devices manually at their respective places (note that we can now use the `async` mount option):

```
# mount -o async /dev/ad0s1d.journal /var
# mount -o async /dev/ad0s1f.journal /usr
```

Edit `/etc/fstab` and update the entries for `/usr` and `/var`:

```
/dev/ad0s1f.journal  /usr      ufs      rw,async  2      2
/dev/ad0s1d.journal  /var      ufs      rw,async  2      2
```

Warning

Make sure the above entries are correct, or you will have trouble starting up normally after you reboot!

Finally, edit `/boot/loader.conf` and add the following line so the [gjournal\(8\)](#) module is loaded at every boot:

```
geom_journal_load="YES"
```

Congratulations! Your system is now set for journaling. You can either type **exit** to return to multi-user mode, or reboot to test your configuration (recommended). During the boot you will see messages like the following:

```
ad0: 76293MB XEC XE800JD-00HBC0 08.02D08 at ata0-master SATA150
GEOM_JOURNAL: Journal 2948326772: ad0s1g contains journal.
GEOM_JOURNAL: Journal 3193218002: ad0s1h contains journal.
GEOM_JOURNAL: Journal 3193218002: ad0s1d contains data.
GEOM_JOURNAL: Journal ad0s1d clean.
GEOM_JOURNAL: Journal 2948326772: ad0s1f contains data.
GEOM_JOURNAL: Journal ad0s1f clean.
```

After an unclean shutdown, the messages will vary slightly, i.e.:

```
GEOM_JOURNAL: Journal ad0s1d consistent.
```

This usually means that [gjournal\(8\)](#) used the information in the journal provider to return the file system to a consistent state.

4.2. Journaling Newly Created Partitions

While the above procedure is necessary for journaling partitions that already contain data, journaling an empty partition is somewhat easier, since both the data and the journal provider can be stored in the same partition. For example, assume a new disk was installed, and a new partition `/dev/ad1s1d` was created. Creating the journal would be as simple as:

```
# gjournal label ad1s1d
```

The journal size will be 1 GB by default. You may adjust it by using the `-s` option. The value can be given in bytes, or appended by `K`, `M` or `G` to denote Kilobytes, Megabytes or Gigabytes respectively. Note that `gjournal` will not allow you to create unsuitably small journal sizes.

For example, to create a 2 GB journal, you could use the following command:

```
# gjournal label -s 2G ad1s1d
```

You can then create a file system on your new partition, and enable journaling using the `-J` option:

```
# newfs -J /dev/ad1s1d.journal
```

4.3. Building Journaling into Your Custom Kernel

If you do not wish to load `geom_journal` as a module, you can build its functions right into your kernel. Edit your custom kernel configuration file, and make sure it includes these two lines:

```
options UFS_GJOURNAL # Note: This is already in GENERIC
```

```
options GEOM_JOURNAL # You will have to add this one
```

Rebuild and reinstall your kernel following the relevant [instructions in the FreeBSD Handbook](#).

Do not forget to remove the relevant “load” entry from `/boot/loader.conf` if you have previously used it.

5. Troubleshooting Journaling

The following section covers frequently asked questions regarding problems related to journaling.

- Q: I am getting kernel panics during periods of high disk activity. How is this related to journaling?
- A: The journal probably fills up before it has a chance to get committed (flushed) to disk. Keep in mind the size of the journal depends on the usage load, and not the size of the data provider. If your disk activity is high, you need a larger partition for the journal. See the note in the [Understanding Journaling](#) section.
- Q: I made some mistake during configuration, and I cannot boot normally now. Can this be fixed some way?
- A: You either forgot (or misspelled) the entry in `/boot/loader.conf`, or there are errors in your `/etc/fstab` file. These are usually easy to fix. Press Enter to get to the default single user shell. Then locate the root of the problem:

```
# cat /boot/loader.conf
```

If the `geom_journal_load` entry is missing or misspelled, the journaled devices are never created. Load the module manually, mount all partitions, and continue with multi-user boot:

```
# gjournal load

GEOM_JOURNAL: Journal 2948326772: ad0s1g contains journal.
GEOM_JOURNAL: Journal 3193218002: ad0s1h contains journal.
GEOM_JOURNAL: Journal 3193218002: ad0s1d contains data.
GEOM_JOURNAL: Journal ad0s1d clean.
GEOM_JOURNAL: Journal 2948326772: ad0s1f contains data.
GEOM_JOURNAL: Journal ad0s1f clean.

# mount -a
# exit
(boot continues)
```

If, on the other hand, this entry is correct, have a look at `/etc/fstab`. You will probably find a misspelled or missing entry. In this case, mount all remaining partitions by hand and continue with the multi-user boot.

- Q: Can I remove journaling and return to my standard file system with Soft Updates?
- A: Sure. Use the following procedure, which reverses the changes. The partitions you created for the journal providers can then be used for other purposes, if you so wish.

Login as root and switch to single user mode:

```
# shutdown now
```

Unmount the journaled partitions:

```
# umount /usr /var
```

Synchronize the journals:

```
# gjournal sync
```

Stop the journaling providers:

```
# gjournal stop ad0s1d.journal
# gjournal stop ad0s1f.journal
```

Clear journaling metadata from all the devices used:

```
# gjournal clear ad0s1d
# gjournal clear ad0s1f
# gjournal clear ad0s1g
# gjournal clear ad0s1h
```

Clear the file system journaling flag, and restore the Soft Updates flag:

```
# tunefs -J disable -n enable ad0s1d

tunefs: gjournal cleared
tunefs: soft updates set

# tunefs -J disable -n enable ad0s1f

tunefs: gjournal cleared
tunefs: soft updates set
```

Remount the old devices by hand:

```
# mount -o rw /dev/ad0s1d /var
# mount -o rw /dev/ad0s1f /usr
```

Edit `/etc/fstab` and restore it to its original state:

```
/dev/ad0s1f    /usr          ufs    rw    2    2
/dev/ad0s1d    /var          ufs    rw    2    2
```

Finally, edit `/boot/loader.conf`, remove the entry that loads the `geom_journal` module and reboot.

6. Further Reading

Journaling is a fairly new feature of FreeBSD, and as such, it is not very well documented yet. You may however find the following additional references useful:

- A [new section on journaling](#) is now part of the FreeBSD Handbook.
- [This post](#) in `freebsd-current` by [gjournal\(8\)](#)'s developer, Paweł Jakub Dawidek <pjd@FreeBSD.org>.
- [This post](#) in `freebsd-questions` by Ivan Voras <ivoras@FreeBSD.org>.
- The manual pages of [gjournal\(8\)](#) and [geom\(8\)](#).
