# Introduction

LOOPS is a package for GAP4 whose purpose is to:

- provide researchers in nonassociative algebra with a powerful computational tool concerning finite loops and quasigroups,
- extend GAP toward the realm of nonassociative structures.

## 1.1 Installation

We assume that you have GAP 4.4 or newer installed on your computer. Download the LOOPS package from the distribution website

```
http://www.math.du.edu/loops
```

and unpack the downloaded file into the `pkg` subfolder of your GAP folder.

After this step, there should be a subfolder `loops` in your `pkg` folder. The package LOOPS can then be loaded to GAP anytime by calling

```
LoadPackage("loops");
```

If you wish to load LOOPS automatically while starting GAP, open the file `loops/PackageInfo.g`, and change `Autoload:=false` to `Autoload:=true` in the file.

## 1.2 Documentation

The documentation is available in several formats: `TEX`, `pdf`, `dvi`, `pdf`, `html`, and as an online help in GAP. All these formats have been obtained directly from the master `TEX` documentation file. Consequently, the different formats of the documentation differ only in their appearance, not in contents.

The documentation can be found in the `doc` folder of LOOPS and also at the LOOPS distribution website.

The online GAP help is available upon installing LOOPS, and can be accessed in the usual way, i.e., upon typing `?command`, GAP displays the section of the LOOPS manual containing information about `command`.

## 1.3 Test files

Test files conforming to the GAP standards are provided for LOOPS. They can be found in the folder `tst` and run in the usual way.

The file `testall.g` runs all tests for LOOPS with the exception of the test `mouflib.tst`. The test `mouflib.tst` builds all Moufang loops contained in the library of LOOPS, and runs for about 10 minutes.

## 1.4 Feedback

We welcome all comments and suggestions on LOOPS, especially those concerning the future development of the package. You can contact us by e-mail.

# 2

# Mathematical background

We assume that you are familiar with the theory of quasigroups and loops, for instance with the textbook of Bruck [2] or Pflugfelder [12]. Nevertheless, we did include definitions and results in this manual in order to unify the terminology and improve the intelligibility of the text. Some general concepts of quasigroups and loops can be found in this chapter. More special concepts are defined throughout the text as needed.

## 2.1 Quasigroups and loops

A set with one binary operation (denoted  $\cdot$  here) is called *groupoid* or *magma*, the latter name being used in GAP. Associative groupoid is known as *semigroup*.

An element  $1$  of a groupoid  $G$  is a *neutral element* or an *identity element* if  $1 \cdot x = x \cdot 1 = x$  for every  $x$  in  $G$ . Semigroup with a neutral element is a *monoid*.

Let  $G$  be a groupoid with neutral element  $1$ . Then an element  $y$  is called a *two-sided inverse* of  $x$  in  $G$  if  $x \cdot y = y \cdot x = 1$ . A monoid in which every element has a two-sided inverse is called a *group*.

Groups can be reached in another way from groupoids, namely through quasigroups and loops.

A *quasigroup*  $Q$  is a groupoid such that the equation  $x \cdot y = z$  has a unique solution in  $Q$  whenever two of the three elements  $x, y, z$  of  $Q$  are specified. Note that multiplication tables of finite quasigroups are precisely *Latin squares*, i.e., a square arrays with symbols arranged so that each symbol occurs in each row and in each column exactly once. A *loop*  $L$  is a quasigroup with a neutral element.

Groups are clearly loops, and one can show easily that an associative quasigroup is a group. Hence the theory of quasigroups and loops is in a sense complementary to the theory of semigroups and monoids.

## 2.2 Translations

Given an element  $x$  of a quasigroup  $Q$  we can associate two permutations of  $Q$  with it: the *left translation*  $L_x : Q \rightarrow Q$  defined by  $y \mapsto x \cdot y$ , and the *right translation*  $R_x : Q \rightarrow Q$  defined by  $y \mapsto y \cdot x$ .

Although it is possible to compose two right (left) translations, the resulting permutation is not necessarily a right (left) translation. The set  $\{L_x; x \in Q\}$  is called the *left section* of  $Q$ , and  $\{R_x; x \in Q\}$  is the *right section* of  $Q$ .

Let  $S_Q$  be the symmetric group on  $Q$ . Then the subgroup  $\text{LMlt}(Q) = \langle L_x | x \in Q \rangle$  of  $S_Q$  generated by all left translations is the *left multiplication group* of  $Q$ . Similarly,  $\text{RMlt}(Q) = \langle R_x | x \in Q \rangle$  is the *right multiplication group* of  $Q$ . The smallest group containing both  $\text{LMlt}(Q)$  and  $\text{RMlt}(Q)$  is called the *multiplication group* of  $Q$  and is denoted by  $\text{Mlt}(Q)$ .

## 2.3 Homomorphisms and homotopisms

Let  $K, H$  be two quasigroups. Then a map  $f : K \rightarrow H$  is a *homomorphism* if  $f(x) \cdot f(y) = f(x \cdot y)$  for every  $x, y \in K$ . If  $f$  is also a bijection, we speak of an *isomorphism*, and the two quasigroups are called *isomorphic*.

The ordered triple  $(\alpha, \beta, \gamma)$  of maps  $\alpha, \beta, \gamma : K \rightarrow H$  is a *homotopism* if  $\alpha(x) \cdot \beta(y) = \gamma(x \cdot y)$  for every  $x, y \in K$ . If the three maps are bijections,  $(\alpha, \beta, \gamma)$  is an *isotopism*, and the two quasigroups are *isotopic*.

Isotopic groups are necessarily isomorphic, but this is certainly not true for nonassociative quasigroups or loops. In fact, every quasigroup is isotopic to a loop, as we shall see.

Let  $(K, \cdot), (K, \circ)$  be two quasigroups defined on the same set  $K$ . Then an isotopism  $(\alpha, \beta, \text{id}_K)$  is called a *principal isotopism*. An important class of principal isotopisms is obtained as follows:

Let  $(K, \cdot)$  be a quasigroup, and let  $f, g$  be elements of  $K$ . Define a new operation  $\circ$  on  $K$  by

$$x \circ y = R_g^{-1}(x) \cdot L_f^{-1}(y),$$

where  $R_g, L_f$  are translations. Then  $(K, \circ)$  is a quasigroup isotopic to  $(K, \cdot)$ , in fact a loop with neutral element  $f \cdot g$ . We call  $(K, \circ)$  a *principal loop isotope* of  $(K, \cdot)$ .

# 3 How the package works

The package consists of three complementary components:

- the core algorithms for quasigroup theoretical notions (see Chapters 4, 5 and 6),
- some specific algorithms, mostly for Moufang loops (see Chapter 7),
- the library of small loops (see Chapter 8).

Although we do not explain the algorithms in detail here, we describe the overarching ideas so that the user should be able to anticipate the capabilities and behavior of LOOPS during computation.

## 3.1 Representing quasigroups

Since the permutation representation in the usual sense is impossible for nonassociative structures, and since the theory of nonassociative presentations is not well understood, we had to resort to multiplication tables to represent quasigroups in GAP.

In order to save storage space, we sometimes use one multiplication table to represent several quasigroups (for instance when a quasigroup is a subquasigroup of another quasigroup).

Consequently, *the package is intended primarily for quasigroups and loops of small order, say up to 1000.*

The categories `IsQuasigroupElement`, `IsLoopElement`, `IsQuasigroup`, and `IsLoop` are declared in LOOPS as follows:

```
DeclareCategory( "IsQuasigroupElement", IsMultiplicativeElement );
DeclareRepresentation( "IsQuasigroupElmRep",
  IsPositionalObjectRep and IsMultiplicativeElement, [1] );
DeclareCategory( "IsLoopElement",
  IsQuasigroupElement and IsMultiplicativeElementWithInverse );
DeclareRepresentation( "IsLoopElmRep",
  IsPositionalObjectRep and IsMultiplicativeElementWithInverse, [1] );
## latin (auxiliary category for GAP to tell apart IsMagma and IsQuasigroup)
DeclareCategory( "IsLatin", IsObject );
DeclareCategory( "IsQuasigroup", IsMagma and IsLatin );
DeclareCategory( "IsLoop", IsQuasigroup and
  IsMultiplicativeElementWithInverseCollection);
```

## 3.2 Conversions between magmas, quasigroups, loops and groups

Whether an object is considered a quasigroup or a loop is a matter of declaration in LOOPS. A declared loop is considered to be a quasigroup, however, a declared quasigroup is *not* considered to be a loop, even if it accidentally possesses a neutral element. It is possible to convert a quasigroup  $Q$  (with or without a neutral element) to a loop using

1 ► `AsLoop( Q )` ○

As we have seen above, the category `IsQuasigroup` is declared in LOOPS so that it is contained in the category `IsMagma`. All standard GAP command for magmas are therefore available for quasigroups and loops, too.

Although groups are quasigroups mathematically, they are not treated as quasigroups in LOOPS. If you wish to apply methods of LOOPS to groups, apply one of the conversions

2 ▶ `AsQuasigroup( G )` O  
 ▶ `AsLoop( G )` O

to the group  $G$ . These conversions fail when  $G$  is infinite and will exhaust all available memory when  $G$  is huge.

For much more information on conversions, see Section 4.6.

### 3.3 Calculating with quasigroups

Although the quasigroups are ultimately represented by multiplication tables, the algorithms are efficient because nearly all calculations are delegated to groups. The connection between quasigroups and groups is facilitated via the above-mentioned translations, and we illustrate it with a few examples:

**Example 1:** This example shows how properties of quasigroups can be translated into properties of translations in a straightforward way.

Let  $Q$  be a quasigroup. We ask if  $Q$  is associative. We can either test if  $(xy)z = x(yz)$  for every  $x, y, z \in Q$ , or we can ask if  $L_{xy} = L_x L_y$  for every  $x, y \in Q$ . Note that since  $L_{xy}, L_x, L_y$  are elements of a permutation group, we do not have to refer directly to the multiplication table once the left translations of  $Q$  are known.

**Example 2:** This example shows how properties of loops can be translated into properties of translations in a way that requires some theory.

A left Bol loop is a loop satisfying  $x(y(xz)) = (x(yx))z$ . We claim (without proof) that a loop  $L$  is left Bol if and only if  $L_x L_y L_x$  is a left translation for every  $x, y \in L$ .

**Example 3:** This example shows that many properties of loops become purely group-theoretical once they are expressed in terms of translations.

A loop is simple if it has no nontrivial congruences. Then it is easy to see that a loop is simple if and only if its multiplication group is a primitive permutation group.

The main idea of the package is therefore to:

- calculate the translations and the associated permutation groups when they are needed,
- store them as attributes,
- use them in algorithms as often as possible.

### 3.4 Naming, viewing and printing quasigroups and their elements

GAP displays information about objects in two modes:

- `View` (default, short),
- `Print` (longer).

Moreover, when the name of an object is set, it is always shown, no matter which display mode is used.

Only loops contained in the libraries of `LOOPS` are named. For instance, the loop obtained via `MoufangLoop( 32, 4 )`, the 4th Moufang loop of order 32, is named `Moufang loop 32/4`.

When  $Q$  is a quasigroup of order  $n$ , it is displayed as `<quasigroup of order n>`. Similarly, a loop of order  $n$  appears as `<loop of order n>`.

The displayed information for a loop  $L$  is enhanced when it is known that  $L$  has certain additional properties. At this point, we support:

```

<associative loop ...>
<extra loop ...>
<Moufang loop ...>
<C loop ...>
<left Bol loop ...>
<right Bol loop ...>
<LC loop ...>
<RC loop ...>
<alternative loop ...>
<left alternative loop ...>
<right alternative loop ...>
<flexible loop ...>

```

The corresponding mathematical definitions and an example can be found in Section 6.4.

It is possible for a loop to have several of the above properties. In such a case, we display the first property on the list that is satisfied.

By default, elements of a quasigroup appear as  $qn$  and elements of a loop appear as  $ln$  in both display modes. The neutral element of a loop is always denoted by  $1l$ . However, one can change the names of elements of a quasigroup  $Q$  or loop  $L$  to *name* with

- 1 ▶ `SetQuasigroupElmName( Q, name )` O
- ▶ `SetLoopElmName( L, name )` O

For quasigroups and loops in the `Print` mode, we display the multiplication table (if it is known), or we display the elements.

In the following example,  $L$  is a loop with two elements.

```

gap> L;
<loop of order 2>
gap> Print( L );
<loop with multiplication table [ [ 1, 2 ], [ 2, 1 ] ]>
gap> Elements( L );
[ 1l, 12 ]
gap> SetLoopElmName( L, "loop_element" ); Elements( L );
[ loop_element1, loop_element2 ]

```

# 4

# Basic methods and attributes

We describe the basic core methods of the LOOPS package in this chapter. The methods discussed here (and more) are declared and implemented in files `quasigrp.gd` and `quasigrp.gi`, respectively.

## 4.1 About Cayley tables

Let  $X = \{x_1, \dots, x_n\}$  be a set and  $\cdot$  a binary operation on  $X$ . Then an  $n$  by  $n$  array with rows and columns bordered by  $x_1, \dots, x_n$ , in this order, is a *Cayley table*, or a *multiplication table* of  $\cdot$ , if the entry in the row  $x_i$  and column  $x_j$  is  $x_i \cdot x_j$ .

A Cayley table is a *quasigroup table* if it is a *Latin square*, i.e., if every entry  $x_i$  appears in every column and every row exactly once.

An annoying feature of quasigroup tables in practice is that they are often not bordered, and it is up to the reader to figure out what is meant. Throughout this manual and in LOOPS, we therefore make the following assumption: *All distinct entries in a quasigroup table must be integers, say  $x_1 < x_2 < \dots < x_n$ , and if no border is specified, we assume that the table is bordered by  $x_1, \dots, x_n$ , in this order.* Note that we do not assume that the distinct entries  $x_1, \dots, x_n$  form the interval  $1, \dots, n$ . The significance of this observation will become clear in Chapter 5.

Finally, we say that a quasigroup table is a *loop table* if the first row and the first column are the same, and if the entries in the first row are ordered in an ascending fashion.

## 4.2 Testing Cayley tables

A square array with integral entries is called a *matrix* in GAP. The following synonymous operations test if a matrix  $T$  is a quasigroup table, as defined above:

- 1 ▶ `IsQuasigroupTable( T )` O
- ▶ `IsQuasigroupCayleyTable( T )` O

The following synonymous operations test if a matrix  $T$  is a loop table:

- 2 ▶ `IsLoopTable( T )` O
- ▶ `IsLoopCayleyTable( T )` O

We would like to call attention to the fact that the package GUAVA also has some operations dealing with Latin squares. In particular, `IsLatinSquare` is declared in GUAVA.

## 4.3 Canonical and normalized Cayley tables

Although we do not assume that a quasigroup table with distinct entries  $x_1 < \dots < x_n$  satisfies  $x_i = i$ , it is often desirable to present quasigroup tables in the latter way. The rather general operation

- 1 ▶ `CanonicalCayleyTable( T )` O

takes any Cayley table  $T$  with distinct entries  $x_1 < \dots < x_m$ , and returns a Cayley table in which  $x_i$  has been replaced by  $i$ .

The operation

- 2 ▶ `NormalizedQuasigroupTable( T )`

makes a quasigroup table  $T$  into a loop table by:

- first calling `CanonicalCayleyTable` to rename the entries to  $1, \dots, n$ ,
- then permuting the columns of  $T$  so that the first row reads  $1, \dots, n$ ,
- and then permuting the rows of  $T$  so that the first column reads  $1, \dots, n$ .

## 4.4 Creating quasigroups and loops manually

When  $T$  is a quasigroup table, the corresponding quasigroup is obtained by

1 ▶ `QuasigroupByCayleyTable( T )` O

Since `CanonicalCayleyTable` is called within the above operation, the resulting quasigroup will have a Cayley table with distinct entries  $1, \dots, n$ .

Here is the analogous operation for a loop table  $T$ :

2 ▶ `LoopByCayleyTable( T )` O

## 4.5 Creating quasigroups and loops from a file

Typing a large multiplication table manually is tedious and error-prone. We have therefore included a universal algorithm in `LOOPS` that reads multiplication tables of quasigroups from a file.

Instead of writing a separate algorithm for each common format, our algorithm relies on the user to provide a bit of information about the input file. Here is an outline of the algorithm, with file named  $F$  and a string  $D$  as arguments on the input:

- read the entire content of  $F$  into a string  $S$ ,
- replace all end-of-line characters in  $S$  by spaces,
- replace by spaces all characters of  $S$  that appear in  $D$ ,
- split  $S$  into maximal substrings without spaces, called *chunks*,
- recognize distinct chunks (let  $n$  be the number of distinct chunks),
- if the number of chunks is not  $n^2$ , report error,
- construct the multiplication table by assigning numerical values  $1, \dots, n$  to chunks, depending on their position among distinct chunks.

The following examples clarify the algorithm and document its versatility. All examples are of the form  $F + D \Rightarrow T$ , meaning that an input file containing  $F$  together with the string  $D$  produce multiplication table  $T$ .

**Example 1:** Data does not have to be arranged into an array of any kind.

$$\begin{array}{cccc} 0 & 1 & 2 & 1 \\ 2 & 0 & 2 & \\ 0 & 1 & & \end{array} + \text{""} \Rightarrow \begin{array}{ccc} 1 & 2 & 3 \\ 2 & 3 & 1 \\ 3 & 1 & 2 \end{array}$$

**Example 2:** Chunks can be any strings.

$$\begin{array}{cc} \text{red} & \text{green} \\ \text{green} & \text{red} \end{array} + \text{""} \Rightarrow \begin{array}{cc} 1 & 2 \\ 2 & 1 \end{array}$$

**Example 3:** A typical table produced by `GAP` is easily parsed by deleting brackets and commas.

$$[[0,1], [1,0]] + "[,]" \Rightarrow \begin{array}{cc} 1 & 2 \\ 2 & 1 \end{array}$$

**Example 4:** A typical `TEX` table with rows separated by lines is also easily converted. Note that we have to use `\\` to make sure that every occurrence of `\` is deleted, since `\\` represents the character `\` in `GAP`.

$$\begin{array}{ccc} x\&y\&z\cr y\&z\&x\cr z\&x\&y \end{array} + "\\cr\&" \Rightarrow \begin{array}{ccc} 1 & 2 & 3 \\ 2 & 3 & 1 \\ 3 & 1 & 2 \end{array}$$

And here are the needed `LOOPS` commands:

1 ▶ `QuasigroupFromFile( F, D )` O

▶ `LoopFromFile( F, D )` O

## 4.6 Conversions

As we have already briefly mentioned, we provide operations that convert between magmas, quasigroups, loops and groups, provided such conversions are possible.

If  $M$  is a declared magma that happens to be a quasigroup, the corresponding quasigroup is returned via

1 ▶ `AsQuasigroup( M )` O

If  $M$  is a magma that happens to be a quasigroup, the operation

2 ▶ `AsLoop( M )` O

returns a loop  $L$  as follows:

- if  $M$  possesses a neutral element  $e$  and  $f$  is the first element of  $M$ , then  $L$  is an isomorphic copy of  $M$  via the transposition  $(e, f)$ ,
- if  $M$  does not possess a neutral element,  $L$  is returned as `PrincipalLoopIsotope( M, M.1, M.1 )`.

Here,

3 ▶ `PrincipalLoopIsotope( Q, f, g )` O

is the principal isotope of a quasigroup  $Q$  using elements  $f, g$  of  $Q$ , as explained in Section 2.3.

Of course, one can obtain a loop from  $M$  in different ways, for instance by normalizing the Cayley table of  $M$ . The three approaches mentioned here can result in different loops in general.

When  $M$  is a declared magma that happens to be a group, then the corresponding group is returned by

4 ▶ `AsGroup( M )` A

Note that the conversions work in both directions, not just toward more special structures. Thus, if  $G$  is a declared group, then `AsLoop( G )` returns the corresponding loop, for instance.

## 4.7 Products of loops

Let  $L1, \dots, Ln$  be a list consisting of loops and groups, where  $n \geq 1$ . Then

1 ▶ `DirectProduct( L1, ..., Ln )` O

returns the direct product of  $L1, \dots, Ln$ .

If there are only groups among  $L1, \dots, Ln$ , a group is returned. Otherwise a loop is returned. If  $n = 1$ ,  $L1$  is returned.

## 4.8 Opposite quasigroups and loops

When  $Q$  is a quasigroup with multiplication  $\cdot$ , the *opposite quasigroup* of  $Q$  is a quasigroup with the same underlying set as  $Q$  and with multiplication  $*$  defined by  $x * y = y \cdot x$ .

Since the quasigroup-theoretical concepts are often chiral (cf. left Bol loops versus right Bol loops), it is useful to have access to the opposite quasigroup of  $Q$ :

1 ▶ `Opposite( Q )` O

## 4.9 Basic attributes

We associate many attributes with quasigroups in order to speed up computation. This section lists the basic attributes of quasigroups and loops.

The list of elements of a quasigroup  $Q$  is obtained by the usual command

1 ▶ `Elements( Q )` A

The Cayley table of a quasigroup  $Q$  is returned with

2 ▶ `CayleyTable( Q )` A

One can use `Display( CayleyTable( Q ) )` for pretty matrix-style output of small Cayley tables.

The neutral element of a loop  $L$  is obtained via

3 ▶ `One( L )` A

If you want to know if a quasigroup  $Q$  has a neutral element, you can find out with the standard function for magmas

4 ▶ `MultiplicativeNeutralElement( Q )` A

The size of a quasigroup  $Q$  is calculated by

5 ▶ `Size( Q )` A

When  $L$  is a *power-associative loop*, i.e., the orders of elements are well-defined in  $L$ , the *exponent* of  $L$  is the smallest positive integer divisible by orders of all elements of  $L$ . The following attribute calculates the exponent without testing for power-associativity:

6 ▶ `Exponent( L )` A

Here is an example for operations and attributes mentioned sofar:

```
gap> A := [ [ 1, 2 ], [ 3, 4 ] ];; B := [ [ 8, 5 ], [ 5, 8 ] ];;
gap> [ IsQuasigroupTable( A ), IsQuasigroupTable( B ), IsLoopTable( B ) ];
[ false, true, false ]
gap> Q := QuasigroupByCayleyTable( B );; CayleyTable( Q );
[ [ 2, 1 ], [ 1, 2 ] ]
gap> CanonicalCayleyTable( B );
[ [ 2, 1 ], [ 1, 2 ] ]
gap> NormalizedQuasigroupTable( B );
[ [ 1, 2 ], [ 2, 1 ] ]
gap> LoopByCayleyTable( last );
<loop of order 2>
gap> [ IsQuasigroup( Q ), IsLoop( Q ), Size( Q ), Elements( Q ) ]
[ true, false, 2, [ q1, q2 ] ]
gap> IsQuasigroupElement( Elements( Q )[ 2 ] );
true
gap> AsLoop( Q );
<loop of order 2>
```

## 4.10 Basic arithmetic operations

Each quasigroup element in GAP knows which quasigroup it belongs to. It is therefore possible to perform arithmetic operations with quasigroup elements without referring to the quasigroup. All elements involved in the calculation must belong to the same quasigroup.

Two elements  $x, y$  of the same quasigroup are multiplied by  $x * y$  in GAP. Since multiplication of elements is ambiguous in the nonassociative case, we always multiply elements from left to right, i.e.,  $x * y * z$  means  $((x * y) * z)$ . Of course, one can specify association by parentheses.

Universal algebraists introduce two additional operations for quasigroups. Namely the *left division*  $x \setminus y$  satisfying  $x \cdot (x \setminus y) = y$ , and the *right division*  $x / y$  satisfying  $(x / y) \cdot y = x$ . These two operations can be found in LOOPS as:

- 1 ▶ `LeftDivision( x, y )` O  
 ▶ `RightDivision( x, y )` O

When  $Q$  is a quasigroup,  $x$  is an element of  $Q$ , and  $S$  is a list of elements of  $Q$ , then

- 2 ▶ `LeftDivision( S, x )` O  
 ▶ `LeftDivision( x, S )` O  
 ▶ `RightDivision( S, x )` O  
 ▶ `RightDivision( x, S )` O

returns the list of elements obtained by performing the respective division of  $S$  by  $x$ , or of  $x$  by  $S$ , using one element of  $S$  at a time.

We also support `/` in place of `RightDivision`. But we do not support `\` in place of `LeftDivision`.

## 4.11 Powers and inverses

Powers of elements are not well-defined in quasigroups, since bracketing can matter even for a single element. We say that the quasigroup  $Q$  is *power-associative*, if for any  $x \in Q$ , the submagma generated by  $x$  is associative.

For magmas and positive integer exponents, GAP defines the powers in the following way:  $x^1 = x$ ,  $x^{2k} = (x^k) \cdot (x^k)$  and  $x^{2k+1} = (x^{2k}) \cdot x$ . One can easily see that this returns  $x^k$  in  $\log_2(k)$  steps. For LOOPS, we have decided to keep this method, hoping that everybody will use it with care for non power-associative quasigroups.

Let  $x$  be an element of a loop  $L$  with neutral element 1. Then the *left inverse*  $x^\lambda$  of  $x$  is the unique element of  $L$  satisfying  $x^\lambda x = 1$ . Similarly, the *right inverse*  $x^\rho$  satisfies  $xx^\rho = 1$ . If  $x^\lambda = x^\rho$ , we call  $x^{-1} = x^\lambda = x^\rho$  the *inverse* of  $x$ .

- 1 ▶ `LeftInverse( x )` O  
 ▶ `RightInverse( x )` O  
 ▶ `Inverse( x )` O

The following examples illustrates the usage of arithmetic operations. `MoufangLoop` will be explained in Chapter 8. In this example, `M.i` coincides with `Elements( M )[ i ]`.

```
gap> M := MoufangLoop( 12, 1 );; x := M.2;
12
gap> [ x * M.3, x^2, x^(-1), Inverse( x ) ];
[ 14, 11, 12, 12 ]
gap> One( M ) = LeftDivision( x, x );
true
```

## 4.12 Associators and commutators

Let  $Q$  be a quasigroup and  $x, y, z \in Q$ . Then the *associator* of  $x, y, z$  is the unique element  $u$  such that  $(xy)z = (x(yz))u$ . The *commutator* of  $x, y$  is the unique element  $v$  such that  $xy = (yx)v$ .

- 1 ▶ `Associator( x, y, z )` O  
 ▶ `Commutator( x, y )` O

## 4.13 Generators

The following two attributes are synonyms of `GeneratorsOfMagma`:

- 1 ▶ `GeneratorsOfQuasigroup( Q )` A  
 ▶ `GeneratorsOfLoop( L )` A

As usual in GAP, one can refer to the  $i$ th generator of a quasigroup  $Q$  by `Q.i`. Note that it is not necessarily the case that `Q.i = Elements( Q )[ i ]`, since the set of generators can be a proper subset of the elements.

It is easy to prove that a quasigroup of order  $n$  can be generated by a subset containing at most  $\log_2 n$  elements. When  $Q$  is a quasigroup

- 2 ▶ `GeneratorsSmallest( Q )` A

returns a generating set  $\{q_0, \dots, q_m\}$  of  $Q$  such that  $Q_0 = \emptyset$ ,  $Q_m = Q$ ,  $Q_i = \langle q_1, \dots, q_i \rangle$ ,  $q_{i+1}$  is the largest element of  $Q \setminus Q_i$ .

# 5 Some methods based on permutation groups

Most calculations in the LOOPS package are delegated to groups, taking advantage of the various permutations and permutation groups associated with quasigroups. This chapter explains in detail how the permutations associated with a quasigroup are calculated, and it also describes some of the core methods of LOOPS based on permutations. Additional core methods can be found in Chapter 6.

## 5.1 Parent of a quasigroup

Let  $Q$  be a quasigroup and  $S$  a subquasigroup of  $Q$ . Since the multiplication in  $S$  coincides with the multiplication in  $Q$ , it is reasonable not to store the multiplication table of  $S$ . However, the quasigroup  $S$  then must know that it is a subquasigroup of  $Q$ . In order to facilitate this relationship, we introduce the attribute

1 ▶ `Parent( Q )` A

for a quasigroup  $Q$ . When  $Q$  is *not* created as a subquasigroup of another quasigroup, the attribute `Parent( Q )` is set to  $Q$ . When  $Q$  is created as a subquasigroup of a quasigroup  $H$ , we let `Parent( Q ) := Parent( H )`. Thus, in effect, `Parent( Q )` is the largest quasigroup from which  $Q$  has been created.

Let  $Q$  be a quasigroup with parent  $P$ , where  $P$  is some  $n$ -element quasigroup. Let  $x$  be an element of  $Q$ . Then `x![1]` is the position of  $x$  among the elements of  $P$ , i.e., `x![1] = Position( Elements( P ), x )`. The position of  $x$  among the elements of  $Q$  is obtained via

2 ▶ `Position( Q, x )` O

While referring to elements of  $Q$  by their positions, we therefore must decide if the positions are meant among the elements of  $Q$ , or among the elements of  $P$ . Since it requires no calculation to obtain `x![1]`, *we always use the position of an element in its parent quasigroup*. In this way, many attributes of a quasigroup, including its Cayley table, are permanently tied to its parent. It is now obvious why we have not insisted on Cayley tables of quasigroups to cover the entire interval  $1, \dots, m$ , for some  $m$ .

When  $S$  is a list of quasigroup elements, not necessarily from the same quasigroup, the operation

3 ▶ `PosInParent( S )`

returns the list of positions of elements of  $S$  in the corresponding parent, i.e., `PosInParent( S )[ i ] = S[ i ]![ 1 ] = Position( Parent( S[ i ] ), S[ i ] )`.

## 5.2 Comparing quasigroups with common parent

Assume that  $A, B$  are two quasigroups with common parent  $Q$ . Let  $G_A, G_B$  be the canonical generating sets of  $A$  and  $B$ , respectively, obtained by the method `GeneratorsSmallest`, described above. Then we define  $A < B$  if and only if  $G_A < G_B$  lexicographically.

Note that if  $A$  is a subquasigroup of  $B$ , we get  $A < B$ , but not necessarily vice versa.

### 5.3 Subquasigroups and subloops

When  $S$  is a subset of a quasigroup  $Q$  (loop  $L$ ), the smallest subquasigroup of  $Q$  (subloop of  $L$ ) generated by  $S$  is returned via:

- 1 ▶ `Subquasigroup( Q, S )` O
- ▶ `Subloop( L, S )` O

In fact, we allow  $S$  to be a list of integers, too, representing the positions of the respective elements in the parent quasigroup (loop).

The following two operations test if a quasigroup (loop)  $S$  is a subquasigroup (subloop) of a quasigroup  $Q$ . They return `true` if and only if  $Q$  and  $S$  have the same parent, and if  $S$  is closed under multiplication in  $Q$ .

- 2 ▶ `IsSubquasigroup( Q, S )` O
- ▶ `IsSubloop( Q, S )` O

### 5.4 Translations and sections

When  $x$  is an element of a quasigroup  $Q$ , the left translation  $L_x$  is a permutation of  $Q$ . In `LOOPS`, all permutations associated with quasigroups and their elements are permutations in the sense of *GAP*, i.e., bijections of some interval  $1, \dots, n$ . Moreover, following our convention, the numerical entries of the permutation point to the positions among elements of `Parent( Q )`, not  $Q$ .

The left and right translations by  $x$  in  $Q$  are obtained by

- 1 ▶ `LeftTranslation( Q, x )` O
- ▶ `RightTranslation( Q, x )` O

The following two attributes calculate the left and right section of a quasigroup  $Q$ :

- 2 ▶ `LeftSection( Q )` A
- ▶ `RightSection( Q )` A

Here is an example illustrating the main features of the subquasigroup construction and the relationship between a quasigroup and its parent.

Note how the Cayley table of the subquasigroup is created only upon explicit demand. Also note that changing the names of elements of a subquasigroup (subloop) automatically changes the names of the elements of the parent subquasigroup (subloop). This is because the elements are shared.

```
gap> M := MoufangLoop( 12, 1 );; S := Subloop( M, [ M.5 ] );
<loop of order 3>
gap> [ Parent( S ) = M, Elements( S ), PosInParent( S ) ];
[ true, [ 11, 13, 15 ], [ 1, 3, 5 ] ]
gap> HasCayleyTable( S );
false
gap> SetLoopElmName( S, "s" );; Elements( S ); Elements( M );
[ s1, s3, s5 ]
[ s1, s2, s3, s4, s5, s6, s7, s8, s9, s10, s11, s12 ]
gap> CayleyTable( S );
[ [ 1, 3, 5 ], [ 3, 5, 1 ], [ 5, 1, 3 ] ]
gap> LeftSection( S );
[ (), (1,3,5), (1,5,3) ]
gap> [ HasCayleyTable( S ), Parent( S ) = M ];
[ true, true ]
gap> L := LoopByCayleyTable( CayleyTable( S ) );; Elements( L );
[ 11, 12, 13 ]
gap> [ Parent( L ) = L, IsSubloop( M, S ), IsSubloop( M, L ) ];
[ true, true, false ]
gap> LeftSection( L );
[ (), (1,2,3), (1,3,2) ]
```

## 5.5 Multiplication groups

The left multiplication group, right multiplication group and the multiplication group of a quasigroup  $Q$  are calculated as follows:

- 1 ▶ `LeftMultiplicationGroup( Q )` A
- ▶ `RightMultiplicationGroup( Q )` A
- ▶ `MultiplicationGroup( Q )` A

Let  $S$  be a subloop of a loop  $L$ . Then the *relative left multiplication group* of  $L$  with respect to  $S$  is the group  $\langle L(x) \mid x \in S \rangle$ , where  $L(x)$  is the left translation by  $x$  in  $Q$  restricted to  $S$ . The *relative right multiplication group* and *relative multiplication group* are defined analogously.

- 2 ▶ `RelativeLeftMultiplicationGroup( L, S )` O
- ▶ `RelativeRightMultiplicationGroup( L, S )` O
- ▶ `RelativeMultiplicationGroup( L, S )` O

## 5.6 Inner mapping groups

The *inner mapping group* of a loop  $L$  is the stabilizer of the unit element in  $\text{Mlt}(L)$ . The elements of this stabilizer are called *inner maps* of  $L$ .

The *left inner mapping group* of a loop  $L$  is the stabilizer of the unit element in  $\text{LMlt}(L)$ . The *right inner mapping group* is defined dually.

- 1 ▶ `InnerMappingGroup( L )` A
- ▶ `LeftInnerMappingGroup( L )` A
- ▶ `RightInnerMappingGroup( L )` A

Here is an example for multiplication groups and inner mapping groups:

```
gap> M := MoufangLoop( 12, 1 );
<Moufang loop 12/1>
gap> LeftSection( M )[ 2 ];
(1,2)(3,4)(5,6)(7,8)(9,12)(10,11)
gap> Mlt := MultiplicationGroup( M ); Inn := InnerMappingGroup( M );
<permutation group of size 2592 with 23 generators>
Group([ (4,6)(7,11), (7,11)(8,10), (2,6,4)(7,9,11), (3,5)(9,11), (8,12,10) ])
gap> Size( Inn );
216
```

## 5.7 Nuclei, commutant, center, and associator subloop

Let  $Q$  be a quasigroup. The *left nucleus*  $N_\lambda(Q)$  of  $Q$  is the set  $\{x \in Q \mid x(yz) = (xy)z \text{ for every } y, z \in Q\}$ . One defines similarly the *middle nucleus*  $N_\mu(Q)$  and the *right nucleus*  $N_\rho(Q)$ . Then the *nucleus*  $N(Q)$  of  $Q$  is the intersection of the three nuclei. These nuclei are calculated in `LOOPS` as follows:

- 1 ▶ `LeftNucleus( Q )` A
- ▶ `MiddleNucleus( Q )` A
- ▶ `RightNucleus( Q )` A
- ▶ `Nuc( Q )` A

Unfortunately, the word `Nucleus` is reserved in the core of `GAP` for a global function with two variables. That is the reason why we have used the abbreviation `Nuc`, which is also common in the literature. However, we support these synonyms of `Nuc`:

- 2 ▶ `NucleusOfLoop( Q )` A
- 3 ▶ `NucleusOfQuasigroup( Q )` A

Since all nuclei are subquasigroups of  $Q$ , they are returned as subquasigroups (resp. subloops).

The *commutant*  $C(Q)$  of  $Q$  is the set  $\{x \in Q \mid xy = yx \text{ for every } y \in Q\}$ . It is also known under the name *Moufang center*. It is obtained via

4 ▶ `Commutant( Q )` A

The center  $Z(Q)$  is defined as the intersection of  $C(Q)$  and  $N(Q)$ , and it is obtained via

5 ▶ `Center( Q )` A

Finally, the *associator subloop* of a loop  $L$  is the subloop of  $L$  generated by all associators of  $L$ . (Note that some authors define the associator subloop as the smallest normal subloop  $A$  of  $L$  such that  $L/A$  is associative. The two definitions are not equivalent in general.)

6 ▶ `AssociatorSubloop( L )` A

## 5.8 Normal subloops

A subloop  $S$  of a loop  $L$  is *normal* if it is invariant under all inner mappings of  $L$ . Normality is tested via:

1 ▶ `IsNormal( L, S )` O

When  $S$  is a subset of a loop  $L$  or a subloop of  $L$ , the *normal closure* of  $S$  in  $L$  is the smallest normal subloop of  $L$  containing  $S$ . It is obtained by

2 ▶ `NormalClosure( L, S )` O

A loop  $L$  is *simple* if all normal subloops of  $L$  are trivial. The corresponding test in LOOPS is:

3 ▶ `IsSimple( L )` O

## 5.9 Factor loops

When  $N$  is a normal subloop of a loop  $L$ , the factor loop  $L/N$  can be obtained directly via the command `L/N`, or by

1 ▶ `FactorLoop( L, N )` O

The natural projection from  $L$  to  $L/N$  is returned by

2 ▶ `NaturalHomomorphismByNormalSubloop( L, N )` O

Here is an illustrating example:

```
gap> M := MoufangLoop( 12, 1 );; S := Subloop( M, [ M.3 ] );
<loop of order 3>
gap> IsNormal( M, S );
true
gap> F := FactorLoop( M, S );
<loop of order 4>
gap> NaturalHomomorphismByNormalSubloop( M, S );
MappingByFunction( <loop of order 12>, <loop of order 4>,
  function( x ) ... end )
```

## 5.10 Nilpotency and central series

The definition of nilpotency and nilpotence class is the same as in group theory. The corresponding commands are:

1 ▶ `NilpotencyClassOfLoop( L )` A

▶ `IsNilpotent( L )` P

When  $L$  is not nilpotent, `NilpotencyClassOfLoop( L )` returns `fail`.

A loop  $L$  is said to be *strongly nilpotent* if its multiplication group is nilpotent. This property is obtained by:

2 ▶ `IsStronglyNilpotent( L )` P

Let  $L$  be a loop. Define *iterated centers*  $Z_i(L)$  as follows:  $Z_0(L) = Z(L)$ ,  $Z_{i+1}(L) = \pi_i^{-1}(Z_i(L))$ , where  $\pi_i$  is the canonical projection  $L \rightarrow L/Z_i(L)$ . The longest series  $Z_i(L), Z_{i-1}(L), \dots, Z_0(L)$  with  $Z_i(L) > Z_{i-1}(L) > \dots > Z_0(L)$  is called the *upper central series* of  $L$ , and is returned via

3 ▶ `UpperCentralSeries( L )` A

The *lower central series*, defined in the usual way, is obtained by

4 ▶ `LowerCentralSeries( L )` A

## 5.11 Solvability

The definition of solvability, derived subloop, derived length, Frattini subloop and Frattini factor size is the same as for groups. Frattini subloop is calculated only for strongly nilpotent loops.

- |     |                                      |   |
|-----|--------------------------------------|---|
| 1 ▶ | <code>IsSolvable( L )</code>         | P |
| ▶   | <code>DerivedSubloop( L )</code>     | A |
| ▶   | <code>DerivedLength( L )</code>      | A |
| ▶   | <code>FrattiniSubloop( L )</code>    | A |
| ▶   | <code>FrattinifactorSize( L )</code> | A |

## 5.12 Isomorphisms and automorphisms

All isomorphisms between two loops can be found with `LOOPS`. The operation

- |     |                                       |   |
|-----|---------------------------------------|---|
| 1 ▶ | <code>IsomorphismLoops( L, M )</code> | O |
|-----|---------------------------------------|---|

returns a single isomorphism between loops  $L, M$  if the loops are isomorphic, and `fail` otherwise.

If an isomorphism exists, it is returned as a permutation  $p$  of  $1, \dots, |L|$ , where  $i^p = j$  means that the  $i$ th element of  $L$  is mapped onto the  $j$ th element of  $M$ . This is true even if  $L$  or  $M$  are not their own parents.

The attribute

- |     |                                     |   |
|-----|-------------------------------------|---|
| 2 ▶ | <code>AutomorphismGroup( L )</code> | A |
|-----|-------------------------------------|---|

returns the automorphism group of the loop  $L$ , with the same convention on permutations as in the case of `IsomorphismLoops`.

Since two isomorphisms differ by an automorphism, all isomorphisms can be obtained by the above two functions.

## 5.13 How are isomorphisms computed

In order to speed up the search for isomorphisms and automorphisms, we first calculate some loop invariants preserved under isomorphisms, and use these invariants to partition the loop into blocks of elements preserved under isomorphisms. These invariants for a loop  $L$  can be obtained via

- |     |                                 |   |
|-----|---------------------------------|---|
| 1 ▶ | <code>Discriminator( L )</code> | O |
|-----|---------------------------------|---|

Since the details are technical, we will not present them here. See [14] or the file `loop_iso.gi` for more.

If two loops have different discriminators, they are not isomorphic. If they have identical discriminators, they may or may not be isomorphic. The operation

- |     |   |   |
|-----|---|---|
| 2 ▶ | <code>AreEqualDiscriminators( D1, D2 )</code> | O |
|-----|---|---|

returns `true` if the discriminators  $D1, D2$  are equal.

# 6 Testing properties of quasigroups and loops

The reader should be aware that although loops are quasigroups, it is often the case in the literature that a property named  $P$  can differ for quasigroups and loops. For instance, a Steiner loop is not necessarily a Steiner quasigroup.

To avoid such ambivalences, we often include the noun `Loop` or `Quasigroup` as part of the name of the property, e.g. `IsSteinerQuasigroup` versus `IsSteinerLoop`.

On the other hand, some properties coincide for quasigroups and loops and we therefore do not include `Loop`, `Quasigroup` as part of the name of the property, e.g. `IsCommutative`.

## 6.1 Associativity, commutativity and generalizations

The following properties test if a quasigroup  $Q$  is associative and commutative:

- 1 ▶ `IsAssociative( Q )` P
- ▶ `IsCommutative( Q )` P

A loop  $L$  is said to be *power-associative* (resp. *diassociative*) if every monogenic subloop of  $L$  (resp. every 2-generated subloop of  $L$ ) is a group.

- 2 ▶ `IsPowerAssociative( L )` P
- ▶ `IsDiassociative( L )` P

## 6.2 Inverse properties

A loop  $L$  has the *left inverse property* if  $x^\lambda(xy) = y$  for every  $x, y \in L$ , where  $x^\lambda$  is the left inverse of  $x$ . Dually,  $L$  has the *right inverse property* if  $(yx)x^\rho = y$  for every  $x, y \in L$ , where  $x^\rho$  is the right inverse of  $x$ . If  $L$  has both the left and right inverse properties, it has the *inverse property*. We say that  $L$  has *two-sided inverses* if  $x^\lambda = x^\rho$  for every  $x \in L$ .

- 1 ▶ `HasLeftInverseProperty( L )` P
- ▶ `HasRightInverseProperty( L )` P
- ▶ `HasInverseProperty( L )` P
- ▶ `HasTwosidedInverses( L )` P

A loop has the *weak inverse property* if  $(xy)^\lambda x = y^\lambda$ . Equivalently, a loop has the weak inverse property if  $x(yx)^\rho = y^\rho$ .

- 2 ▶ `HasWeakInverseProperty( L )` P

According to [1], a loop  $L$  has the *automorphic inverse property*

if  $(xy)^\lambda = x^\lambda y^\lambda$ , or, equivalently,  $(xy)^\rho = x^\rho y^\rho$ . (In particular, when  $L$  has two-sided inverses and the automorphic inverse property, it satisfies  $(xy)^{-1} = x^{-1}y^{-1}$ .) Similarly,  $L$  has the *antiautomorphic inverse property* if  $(xy)^\lambda = y^\lambda x^\lambda$ , or, equivalently,  $(xy)^\rho = y^\rho x^\rho$ .

- 3 ▶ `HasAutomorphicInverseProperty( L )` P
- ▶ `HasAntiautomorphicInverseProperty( L )` P

The following implications among inverse properties hold and are implemented in `LOOPS`:

- Inverse property implies left and right inverse properties, two-sided inverses, weak inverse property, and antiautomorphic inverse property.
- Antiautomorphic inverse property loops have two-sided inverses.
- If a loop has any two of the left inverse property, right inverse property, weak inverse property or antiautomorphic inverse property, it also has the inverse property.

### 6.3 Some properties of quasigroups

A quasigroup  $Q$  is *semisymmetric* if  $(xy)x = y$  for every  $x, y \in Q$ . Equivalently,  $Q$  is semisymmetric if  $x(yx) = y$  for every  $x, y \in Q$ . A semisymmetric commutative quasigroup is known as *totally symmetric*. Totally symmetric quasigroups are precisely quasigroups satisfying  $xy = x \setminus y = x / y$ .

- 1 ▶ `IsSemisymmetric( Q )` P  
 ▶ `IsTotallySymmetric( Q )` P

A quasigroup  $Q$  is *idempotent* if  $x^2 = x$  for every  $x \in Q$ . Idempotent totally symmetric quasigroups are known as *Steiner quasigroups*. A quasigroup  $Q$  is *unipotent* if  $x^2 = y^2$  for every  $x, y \in Q$ .

- 2 ▶ `IsIdempotent( Q )` P  
 ▶ `IsSteinerQuasigroup( Q )` P  
 ▶ `IsUnipotent( Q )` P

A quasigroup is *left distributive* if it satisfies  $x(yz) = (xy)(xz)$ . Similarly, it is *right distributive* if it satisfies  $(xy)z = (xz)(yz)$ . A *distributive quasigroup* is a quasigroup that is both left and right distributive. A quasigroup is called *entropic* or *medial* if it satisfies  $(xy)(zw) = (xz)(yw)$ .

- 3 ▶ `IsLeftDistributive( Q )` P  
 ▶ `IsRightDistributive( Q )` P  
 ▶ `IsDistributive( Q )` P  
 ▶ `IsEntropic( Q )` P  
 ▶ `IsMedial( Q )` P

In order to be compatible with GAP's terminology, we also support the synonyms

- 4 ▶ `IsLDistributive( Q )` P  
 ▶ `IsRDistributive( Q )` P

for `IsLeftDistributive` and `IsRightDistributive`, respectively.

### 6.4 Loops of Bol-Moufang type and related properties

Following [7] and [13], a variety of loops is said to be of *Bol-Moufang type* if it is defined by a single *identity of Bol-Moufang type*, i.e., by an identity that:

- contains the same 3 variables on both sides,
- exactly one of the variables occurs twice on both sides,
- the variables occur in the same order on both sides.

It is proved in [13] that there are 13 varieties of nonassociative loops of Bol-Moufang type. These are:

- *left alternative loops*, defined by  $x(xy) = (xx)y$ ,
- *right alternative loops*, defined by  $x(yy) = (xy)y$ ,
- *left nuclear square loops*, defined by  $(xx)(yz) = ((xx)y)z$ ,
- *middle nuclear square loops*, defined by  $x((yy)z) = (x(yy))z$ ,
- *right nuclear square loops*, defined by  $x(y(zz)) = (xy)(zz)$ ,
- *flexible loops*, defined by  $x(yx) = (xy)x$ ,
- *left Bol loops*, defined by  $x(y(xz)) = (x(yz))x$ , always left alternative,
- *right Bol loops*, defined by  $x((yz)y) = ((xy)z)y$ , always right alternative,
- *LC-loops*, defined by  $(xx)(yz) = (x(xy))z$ , always left alternative, left and middle nuclear square,
- *RC-loops*, defined by  $x((yz)z) = (xy)(zz)$ , always right alternative, right and middle nuclear square,
- *Moufang loops*, defined by  $(xy)(zx) = (x(yz))x$ , always flexible, left and right Bol,
- *C-loops*, defined by  $x(y(yz)) = ((xy)y)z$ , always LC and RC,
- *extra loops*, defined by  $x(y(zx)) = ((xy)z)x$ , always Moufang and C.

Note that although some of the defining identities are not of Bol-Moufang type, they are equivalent to a Bol-Moufang identity. Moreover, many varieties are defined in several ways, by equivalent identities of Bol-Moufang type.

There are several varieties related to loops of Bol-Moufang type. A loop is said to be *alternative* if it is both left and right alternative, and *nuclear square* if it is left, middle and right nuclear square.

Here are the corresponding **LOOPS** commands (argument  $L$  indicates that the property applies only to loops, argument  $Q$  indicates that the property applies also to quasigroups):

1 ▶	IsExtraLoop( $L$ )	P
▶	IsMoufangLoop( $L$ )	P
▶	IsCLoop( $L$ )	P
▶	IsLeftBolLoop( $L$ )	P
▶	IsRightBolLoop( $L$ )	P
▶	IsLCLoop( $L$ )	P
▶	IsRCLoop( $L$ )	P
▶	IsLeftNuclearSquareLoop( $L$ )	P
▶	IsMiddleNuclearSquareLoop( $L$ )	P
▶	IsRightNuclearSquareLoop( $L$ )	P
▶	IsNuclearSquareLoop( $L$ )	P
▶	IsFlexible( $Q$ )	P
▶	IsLeftAlternative( $Q$ )	P
▶	IsRightAlternative( $Q$ )	P
▶	IsAlternative( $Q$ )	P

While listing the varieties of loops of Bol-Moufang type, we have also listed all inclusions among them. These inclusions are built into **LOOPS**.

The following trivial example shows some of the implications and the naming conventions of **LOOPS** at work:

```
gap> L := LoopByCayleyTable( [ [ 1, 2 ], [ 2, 1 ] ] );
<loop of order 2>
gap> [ IsLeftBolLoop( L ), L ]
[ true, <left Bol loop of order 2> ]
gap> [ HasIsLeftAlternativeLoop( L ), IsLeftAlternativeLoop( L ) ];
[ true, true ]
gap> [ HasIsRightBolLoop( L ), IsRightBolLoop( L ) ];
[ false, true ]
gap> L;
<Moufang loop of order 2>
gap> [ IsAssociative( L ), L ];
[ true, <associative loop of order 2> ]
```

The analogous terminology for quasigroups of Bol-Moufang type is not standard yet, and hence is not supported in **LOOPS**.

## 6.5 Conjugacy closed loops and related properties

A loop is *left* (resp. *right*) *conjugacy closed* if its left (resp. right) translations are closed under composition. A loop that is both left and right conjugacy closed is called *conjugacy closed*. It is common to refer to these loops as LCC-, RCC-, CC-loops, respectively.

1 ▶	IsLCCLoop( $L$ )	P
▶	IsRCCLoop( $L$ )	P
▶	IsCCLoop( $L$ )	P

The equivalence  $LCC + RCC = CC$  is built into **LOOPS**.

A loop is *Osborn* if it satisfies  $x(yz \cdot x) = (x^\lambda \backslash y)(zx)$ , where  $x^\lambda$  is the left inverse of  $x$ . Both Moufang loops and CC-loops are Osborn.

2 ▶	IsOsbornLoop( $L$ )	P
-----	---------------------	---

## 6.6 Additional varieties of loops

A left (resp. right) Bol loop with the automorphic inverse property is known as *left* (resp. *right*) *Bruck loop*. Bruck loops are also known as *K-loops*.

- 1 ▶ `IsLeftBruckLoop( L )` P
- ▶ `IsLeftKLoop( L )` P
- ▶ `IsRightBruckLoop( L )` P
- ▶ `IsRightKLoop( L )` P

*Steiner loop* is an inverse property loop of exponent 2.

- 2 ▶ `IsSteinerLoop( L )` P

# 7

## Specific methods

This chapter describes methods of LOOPS that apply to some special loops, mostly Moufang loops.

### 7.1 Moufang modifications

Aleš Drápal discovered two prominent families of extensions of Moufang loops. These extensions can be used to obtain many, perhaps all, nonassociative Moufang loops of order at most 64. We call these two constructions *Moufang modifications*. The library of Moufang loops included with LOOPS is based on Moufang modifications. We describe the two modifications briefly here. See [6] for details.

Assume that  $L$  is a Moufang loop with normal subloop  $S$  such that  $L/S$  is a cyclic group of order  $2m$ . Let  $h \in S \cap Z(L)$ . Let  $\alpha$  be a generator of  $L/S$  and write  $L = \bigcup_{i \in M} \alpha^i$ , where  $M = \{-m+1, \dots, m\}$ . Let  $\sigma : \mathbb{Z} \rightarrow M$  be defined by  $\sigma(i) = 0$  if  $i \in M$ ,  $\sigma(i) = 1$  if  $i > m$ , and  $\sigma(i) = -1$  if  $i < -m+1$ . Introduce a new multiplication  $*$  on  $L$  defined by

$$x * y = xyh^{\sigma(i+j)},$$

where  $x \in \alpha^i$ ,  $y \in \alpha^j$ ,  $i \in M$ ,  $j \in M$ . Then  $(L, *)$  is a Moufang loop, a *cyclic modification* of  $L$ .

When  $L$ ,  $S$ ,  $\alpha$ ,  $h$  are as above and when  $a$  is any element of  $\alpha$ , the corresponding cyclic modification is obtained via

1 ► LoopByCyclicModification(  $L$ ,  $S$ ,  $a$ ,  $h$  ) F

Now assume that  $L$  is a Moufang loop with normal subloop  $S$  such that  $L/S$  is a dihedral group of order  $4m$ , with  $m \geq 1$ . Let  $M$  and  $\sigma$  be defined as in the cyclic case. Let  $\beta, \gamma \in L/S$  be two involutions of  $L/S$  such that  $\alpha = \beta\gamma$  generates a cyclic subgroup of  $L/S$  of order  $2m$ . Let  $e \in \beta$  and  $f \in \gamma$  be arbitrary. Then  $L$  can be written as a disjoint union  $L = \bigcup_{i \in M} (\alpha^i \cup e\alpha^i)$ , and also  $L = \bigcup_{i \in M} (\alpha^i \cup \alpha^i f)$ . Let  $G_0 = \bigcup_{i \in M} \alpha^i$ , and  $G_1 = L \setminus G_0$ . Let  $h \in S \cap N(L) \cap Z(G_0)$ . Introduce a new multiplication  $*$  on  $L$  defined by

$$x * y = xyh^{(-1)^r \sigma(i+j)},$$

where  $x \in \alpha^i \cup e\alpha^i$ ,  $y \in \alpha^j \cup \alpha^j f$ ,  $i \in M$ ,  $j \in M$ ,  $y \in G_r$ ,  $r \in \{0, 1\}$ . Then  $(L, *)$  is a Moufang loop, a *dihedral modification* of  $L$ .

When  $L$ ,  $S$ ,  $e$ ,  $f$  and  $h$  are as above, the corresponding dihedral modification is obtained via

2 ► LoopByDihedralModification(  $L$ ,  $S$ ,  $e$ ,  $f$ ,  $h$  ) F

In order to apply the cyclic and dihedral modifications, it is beneficial to have access to a class of nonassociative Moufang loops. The following construction is due to Chein:

Let  $G$  be a group. Let  $\overline{G} = \{\overline{g}; g \in G\}$  be a set of new elements. Define multiplication  $*$  on  $L = G \cup \overline{G}$  by

$$g * h = gh, \quad g * \overline{h} = \overline{hg}, \quad \overline{g} * h = \overline{gh^{-1}}, \quad \overline{g} * \overline{h} = h^{-1}g,$$

where  $g, h \in G$ . Then  $L = M(G, 2)$  is a Moufang loop that is nonassociative if and only if  $G$  is nonabelian.

The loop  $M(G, 2)$  can be obtained from a finite group  $G$  with

3 ► LoopMG2(  $G$  ) F

## 7.2 Triality for Moufang loops

Let  $G$  be a group and  $\sigma, \rho$  be automorphisms of  $G$ , satisfying  $\sigma^2 = \rho^3 = (\sigma\rho)^2 = 1$ . We write the automorphisms of a group as exponents and  $[g, \sigma]$  for  $g^{-1}g^\sigma$ . We say that the triple  $(G, \rho, \sigma)$  is a *group with triality* if  $[g, \sigma][g, \sigma]^\rho[g, \sigma]^{\rho^2} = 1$  holds for all  $g \in G$ . It is known that one can associate a group with triality  $(G, \rho, \sigma)$  in a canonical way with a Moufang loop  $L$ . See [11] for more details.

For any Moufang loop  $L$ , we can calculate the triality group as a permutation group acting on  $3|L|$  points. If the multiplication group of  $L$  is polycyclic, then we can also represent the triality group as a pc group. In both cases, the automorphisms  $\sigma$  and  $\rho$  are in the same family as the elements of  $G$ .

Given a Moufang loop  $L$ , the function

1 ► `TrialityPermGroup( L )` F

returns a record  $[G, \rho, \sigma]$ , where  $G$  is the group with triality associated with  $L$ , and  $\rho, \sigma$  are the corresponding triality automorphisms.

The function

2 ► `TrialityPcGroup( L )` F

differs from `TrialityPermGroup` only in that  $G$  is returned as a pc group.

# 8 Libraries of small loops

Libraries of small loops form an integral part of LOOPS. We describe them here.

## 8.1 A typical library

A library named *my Library* is stored in file `data/mylibrary.tbl`, and the corresponding data structure is named `my_library_data`.

The array `my_library_data` consists of three lists

- `my_library_data[ 1 ]` is a list of orders for which there is at least one loop in the library,
- `my_library_data[ 2 ][ k ]` is the number of loops of order `my_library_data[ 1 ][ k ]` in the library,
- `my_library_data[ 3 ][ s ]` contains data necessary to produce the *s*th loop in the library.

The format of `my_library_data[ 3 ]` depends on the particular library and is not standardized in any way. The user can retrieve the *m*th loop of order *n* from library named *my Library* according to the template

1 ▶ `MyLibraryLoop( n, m )` F

It is also possible to obtain the same loop with

2 ▶ `LibraryLoop( name, n, m )` F

where *name* is the name of the library.

For example, when the library is called *left Bol*, the corresponding data file is called `data/leftbol.tbl`, the corresponding data structure is named `left_bol_data`, and the *m*th left Bol loop of order *n* is obtained via

```
LeftBolLoop( n, m )
```

or via

```
LibraryLoop("left Bol", n, m )
```

We are now going to describe the individual libraries in detail. A brief information about the library named *name* can also be obtained in LOOPS with

3 ▶ `DisplayLibraryInfo( name )` F

## 8.2 Left Bol loops

The library named *left Bol* contains all 6 nonassociative left Bol loops of order 8. Following the general pattern, the *m*th nonassociative left Bol loop of order *n* is obtained by

1 ▶ `LeftBolLoop( n, m )` F

We intend to enlarge this library significantly in future versions of LOOPS, when the classification of small Bol loops is completed.

### 8.3 Small Moufang loops

The library named *Moufang* contains all nonassociative Moufang loops of order less than 64, and additional 4262 nonassociative Moufang loops of order 64. It is possible that there are no other nonassociative Moufang loops of order 64 than those contained in the library.

The  $m$ th nonassociative Moufang loop of order  $n$  is obtained by

1 ▶ `MoufangLoop( n, m )` F

For  $n \leq 63$ , our catalog numbers coincide with those of Goodaire et al. [8].

The extent of the library is summarized below:

order	12	16	20	24	28	32	36	40	42	44	48	52	54	56	60	64
loops in the library	1	5	1	5	1	71	4	5	1	1	51	1	2	4	5	4262

The *octonion loop* of order 16 (i.e., the multiplication loop of the  $\pm$  basis elements in the 8-dimensional standard real octonion algebra) is `MoufangLoop( 16, 3 )`.

Since we would like to know if there are additional nonassociative Moufang loops of order 64, we have implemented the function

2 ▶ `IsomorphismTypeOfMoufangLoop( L )` F

If  $L$  is a Moufang loop cataloged in `LOOPS` as the  $m$ th Moufang loop of order  $n$ , the function returns  $[[n, m], p]$ , where  $p$  is a permutation of  $[1, \dots, n]$  that is an isomorphism from  $L$  to the cataloged copy of  $L$ . If  $n = 64$  and  $L$  is Moufang loop not cataloged in `LOOPS`, the user is prompted to contact the authors of `LOOPS`.

In order to speed up the function `IsomorphismTypeOfMoufangLoop`, we have precalculated and stored in the data file `data\moufang-discriminators.tbl` the discriminators of all Moufang loops in the library. The file is rather large (850 KB), and took about 20 minutes to precalculate. You can delete the file if you will not use `IsomorphismTypeOfMoufangLoop`.

```
gap> D := DirectProduct( MoufangLoop( 16, 2 ), CyclicGroup( 2 ) );
<loop of order 32>
gap> IsomorphismTypeOfMoufangLoop( D );
[ [ 32, 2 ], (2,3,12,20,11,29,23,13,30,31,28,27,22,15,32,18,10,19,16,24,14,
25,21,8,7,6,9,17,5) ]
```

### 8.4 Steiner loops

Here is how the library *Steiner* is described within `LOOPS`:

```
gap> DisplayLibraryInfo( "Steiner" );
The library contains all nonassociative Steiner loops of order less or equal to 16.
It also contains the associative Steiner loops of order 4 and 8.
-----
Extent of the library:
  1 loop of order 4
  1 loop of order 8
  1 loop of order 10
  2 loops of order 14
  80 loops of order 16
true
```

The  $m$ th Steiner loop of order  $n$  is obtained by

1 ▶ `SteinerLoop( n, m )` F

Our catalog numbers coincide with those of Colbourn and Rosa [4].

## 8.5 CC-loops

By results of Kunen [9], for every odd prime  $p$  there are precisely 3 nonassociative conjugacy closed loops of order  $p^2$ . Csörgő and Drápal [5] described these 3 loops by multiplicative formulas on  $\mathbb{Z}_{p^2}$  and  $\mathbb{Z}_p \times \mathbb{Z}_p$ .

**Case  $m = 1$ :** Let  $k$  be the smallest positive integer relatively prime to  $p$  and such that  $k$  is a square modulo  $p$  (i.e.,  $k = 1$ ). Define multiplication on  $\mathbb{Z}_{p^2}$  by  $x \cdot y = x + y + kpx^2y$ .

**Case  $m = 2$ :** Let  $k$  be the smallest positive integer relatively prime to  $p$  and such that  $k$  is not a square modulo  $p$ . Define multiplication on  $\mathbb{Z}_{p^2}$  by  $x \cdot y = x + y + kpx^2y$ .

**Case  $m = 3$ :** Define multiplication on  $\mathbb{Z}_p \times \mathbb{Z}_p$  by  $(x, a)(y, b) = (x + y, a + b + x^2y)$ .

Moreover, Wilson [15] constructed a nonassociative CC-loop of order  $2p$  for every odd prime  $p$ , and Kunen [9] showed that there are no other nonassociative CC-loops of this order. Here is the construction:

Let  $N$  be an additive cyclic group of order  $n > 2$ ,  $N = \langle 1 \rangle$ . Let  $G$  be the additive cyclic group of order 2. Define multiplication on  $L = G \times N$  as follows:

$$\begin{aligned} (0, m)(0, n) &= (0, m + n), & (0, m)(1, n) &= (1, -m + n), \\ (1, m)(0, n) &= (1, m + n), & (1, m)(1, n) &= (0, 1 - m + n). \end{aligned}$$

The CC-loops described above can be obtained by

1 ► `CCLoop( n, m )` F

## 8.6 Paige loops

*Paige loops* are nonassociative finite simple Moufang loops. By [10], there is precisely one Paige loop for every finite field  $\text{GF}(q)$ .

The library named *Paige* contains the smallest nonassociative simple Moufang loop

1 ► `PaigeLoop( 2 )` F

## 8.7 Interesting loops

The library named *interesting* contains some loops that are illustrative for the theory of loops. At this point, the library contains a nonassociative loop of order 5, a nonassociative nilpotent loop of order 6, a nonMoufang left Bol loop of order 16, and the loop of sedenions of order 32 (sedenions generalize octonions).

The loops are obtained with

1 ► `InterestingLoop( n, m )` F

# A

# Files

Below is a list of all relevant files forming the LOOPS package. Some technical files are not mentioned. You do not need any of this information unless you want to modify the package. All paths are relative to the loops folder.

```
../README.loops (installation and usage instructions)
init.g (declarations)
PackageInfo.g (loading info for GAP 4.4)
read.g (implementations)
data/cc.tbl (library of CC-loops)
data/interesting.tbl (library of interesting loops)
data/leftbol.tbl (library of left Bol loops)
data/moufang.tbl (library of Moufang loops)
data/moufang_discriminators.tbl (precalculated data needed for isomorphisms of Moufang loops)
data/paige.tbl (library of Paige loops)
data/steiner.tbl (library of Steiner loops)
doc/manual.* (documentation files)
gap/banner.g (banner of LOOPS)
gap/examples.gd .gi (methods for libraries of loops)
gap/loop_iso.gd .gi (methods for isomorphisms of loops)
gap/moufang_modifications.gd .gi (methods for Moufang modifications)
gap/quasigrp.gd .gi (core methods)
gap/triality.gd .gi (methods for triality of Moufang loops)
tst/auto.tst (test file for isomorphisms and automorphisms)
tst/lib.tst (test file for libraries of loops, except Moufang loops)
tst/mouflib.tst (test file for library of Moufang loops)
tst/nilpot.tst (test file for nilpotency and triality)
tst/quasigrp.tst (test file for core methods)
tst/testall.g (batch for all tests files)
```

# B

# Filters built into the package

Many implications among properties of loops are built directly into LOOPS. A sizeable portion of these properties are of trivial character or are based on definitions (e.g., alternative loops = left alternative loops + right alternative loops). The remaining implications are theorems.

All filters of LOOPS are summarized below, using the GAP convention that the property on the left is implied by the property (properties) on the right.
